

Programming Exercise: User Registration Validator

Problem Statement

You are developing a simple User Registration System for an iOS application. Your task is to write a Swift program that validates a user's registration details and displays appropriate messages based on different conditions.

Use the following input values:

```
let firstName = "KaMaKshi"  
let lastName = "Goyal"  
let username = "KamaKshi_Goyal"  
let password = "Swift@123"  
let email = "kamakshi.goyal@mitwpu.edu.in"
```

Tasks

1. Write a Swift program to perform the following operations:

Display a welcome message using string interpolation in the format:

“Welcome, Kamakshi Goyal!”

(The first and last names should be displayed in a properly formatted manner.)

2. Validate the username by checking the following:

- It starts with the first three letters of the user's first name (case-insensitive).
- It contains an underscore (_).

Display an appropriate message indicating whether the username is valid.

3. Validate the password by checking whether:

- It contains at least 8 characters.
- It contains the "@" symbol.

Display suitable messages for each validation.

4. Validate the email address by checking whether:

- It contains "@".
- It ends with the suffix .edu.in.

If both conditions are satisfied, display:

“Educational email verified.”

Otherwise, display an appropriate error message.

5. Determine the type of the first character of the password using a switch statement.

If the first character is a vowel (a, e, i, o, u), print:

“Password starts with a vowel.”

Otherwise, print:

“Password starts with a consonant, number, or symbol.”

6. Compare the first name and last name in a case-insensitive manner and display whether they are the same or different.

Create an empty string named summary.

If it is empty, initialize it with:

“Registration Successful”

Append the following text using string concatenation:

“- Welcome to the iOS Development Centre!”

Print the final summary.
